I. ANALYTIC SOLUTIONS OF THE KITAEV TRIANGLE

In this section we present some analytic results related to the 3-site Kitaev triangle.

We start from the 1D Kitaev chain Hamiltonian with complex nearest-neighbor hopping $-te^{i\phi}$ and p -wave pairing $\Delta e^{i\theta}$ in the Kitaev limit ($t = \Delta > 0, \mu = 0$):

$$H = \sum_n (-te^{i\phi} c_n^\dagger c_{n+1} + \Delta e^{i\theta} c_n c_{n+1} + \text{h.c.}) \quad (1)$$

In the Majorana fermion basis $a_n = c_n + c_n^\dagger$, $b_n = -i(c_n - c_n^\dagger)$ the Hamiltonian becomes

$$H = -\frac{it}{2} \sum_n [(S_\phi - S_\theta) a_n a_{n+1} + (S_\phi + S_\theta) b_n b_{n+1} + (C_\phi - C_\theta) a_n b_{n+1} - (C_\phi + C_\theta) b_n a_{n+1}] \quad (2)$$

where $S_\phi \equiv \sin \phi$, $C_\phi \equiv \cos \phi$, etc. Therefore, when $\phi = \theta$, a_n becomes decoupled from a_{n+1} and b_{n+1} , and a_1 drops out from the Hamiltonian. Similarly, when $\phi = \theta + \pi$, b_1 becomes isolated. To find the other MZM, we note that when $\phi = \theta$, terms involving a_N and b_N in the Hamiltonian are

$$H_N = -itb_{N-1}(S_\phi b_N - C_\phi a_N). \quad (3)$$

Considering the unitary transformation

$$\begin{pmatrix} a'_N \\ b'_N \end{pmatrix} \equiv \begin{pmatrix} C_\phi & -S_\phi \\ S_\phi & C_\phi \end{pmatrix} \begin{pmatrix} a_N \\ b_N \end{pmatrix} \quad (4)$$

we have

$$H_N = itb_{N-1}a'_N \quad (5)$$

Therefore the other MZM is $b'_N = S_\phi a_N + C_\phi b_N$. Similarly, when $\phi = \theta + \pi$ the other MZM is $a'_N \equiv C_\phi a_N - S_\phi b_N$.

For the 3-site Kitaev triangle at the initial configuration ϕ_1 , if the three edges were isolated from each other, the MZM would have been

$$1-2: \quad a_1, b_2 \quad (6)$$

$$2-3: \quad b_2, \frac{1}{2}a_3 + \frac{\sqrt{3}}{2}b_3$$

$$3-1: \quad a_1, \frac{\sqrt{3}}{2}a_3 + \frac{1}{2}b_3$$

One can therefore see that the two MZM at site 3 are not compatible with each other.

We next solve for the excited states of the Kitaev triangle at the initial configuration ϕ_1 . The Hamiltonian in the Majorana basis is

$$H = -\frac{it}{2} \left(-2b_1a_2 - \sqrt{3}a_2a_3 + a_2b_3 + \sqrt{3}b_1b_3 - b_1a_3 \right) = \frac{1}{2}\Gamma h \Gamma^T \quad (7)$$

$$\Gamma \equiv (b_1, a_2, a_3, b_3)$$

$$h \equiv -it \begin{pmatrix} 0 & -1 & -\frac{1}{2} & \frac{\sqrt{3}}{2} \\ 1 & 0 & -\frac{\sqrt{3}}{2} & \frac{1}{2} \\ \frac{1}{2} & \frac{\sqrt{3}}{2} & 0 & 0 \\ -\frac{\sqrt{3}}{2} & -\frac{1}{2} & 0 & 0 \end{pmatrix} = t \left(-\frac{1}{2}\sigma_0\tau_y - \frac{1}{2}\sigma_z\tau_y - \frac{1}{2}\sigma_y\tau_z + \frac{\sqrt{3}}{2}\sigma_x\tau_y \right)$$

h has the following symmetry:

$$O = \left(\frac{\sqrt{3}}{2} \sigma_x - \frac{1}{2} \sigma_z \right) \tau_y \quad (8)$$

We therefore rotate the Hamiltonian so that O becomes diagonal using the following unitary operator

$$U = e^{-\frac{i\pi}{3} \sigma_y} \otimes e^{i\frac{\pi}{4} \tau_x} \quad (9)$$

which leads to

$$U^\dagger O U = \text{Diag}(1, -1, -1, 1) \quad (10)$$

U therefore block-diagonalizes h as

$$U^\dagger h U = \frac{t}{2} \begin{pmatrix} 1 & & & -1 \\ & -1 & 1 & \\ & 1 & -3 & \\ -1 & & & 3 \end{pmatrix} \quad (11)$$

which can then be diagonalized by

$$V = \begin{pmatrix} \frac{1+\sqrt{2}}{\sqrt{4+2\sqrt{2}}} & 0 & \frac{1-\sqrt{2}}{\sqrt{4-2\sqrt{2}}} & 0 \\ 0 & \frac{1+\sqrt{2}}{\sqrt{4+2\sqrt{2}}} & 0 & \frac{1-\sqrt{2}}{\sqrt{4-2\sqrt{2}}} \\ 0 & \frac{1}{\sqrt{4+2\sqrt{2}}} & 0 & \frac{1}{\sqrt{4-2\sqrt{2}}} \\ \frac{1}{\sqrt{4+2\sqrt{2}}} & 0 & \frac{1}{\sqrt{4-2\sqrt{2}}} & 0 \end{pmatrix} \quad (12)$$

as

$$V^\dagger U^\dagger h U V = t \times \text{Diag} \left(1 - \frac{\sqrt{2}}{2}, -1 + \frac{\sqrt{2}}{2}, 1 + \frac{\sqrt{2}}{2}, -1 - \frac{\sqrt{2}}{2} \right) \quad (13)$$

We therefore have the two lowest excited states with eigenenergies $\pm t(1 - \frac{\sqrt{2}}{2})$

$$\begin{aligned} \psi_{+1} &= \Gamma U \begin{pmatrix} \frac{1+\sqrt{2}}{\sqrt{4+2\sqrt{2}}} \\ 0 \\ 0 \\ \frac{1}{\sqrt{4+2\sqrt{2}}} \end{pmatrix} = \Gamma \times \frac{1}{4\sqrt{2+\sqrt{2}}} \begin{pmatrix} 1 + \sqrt{2} - \sqrt{3}i \\ (1 + \sqrt{2})i - \sqrt{3} \\ i + \sqrt{3} + \sqrt{6} \\ 1 + (\sqrt{3} + \sqrt{6})i \end{pmatrix} \\ \psi_{-1} &= \Gamma U \begin{pmatrix} 0 \\ \frac{1+\sqrt{2}}{\sqrt{4+2\sqrt{2}}} \\ \frac{1}{\sqrt{4+2\sqrt{2}}} \\ 0 \end{pmatrix} = \Gamma \times \frac{1}{4\sqrt{2+\sqrt{2}}} \begin{pmatrix} (1 + \sqrt{2})i - \sqrt{3} \\ 1 + \sqrt{2} - \sqrt{3}i \\ 1 + (\sqrt{3} + \sqrt{6})i \\ i + \sqrt{3} + \sqrt{6} \end{pmatrix} \end{aligned} \quad (14)$$

The first excited states can therefore be understood as a hybridization between the “bulk” states of the 1-2 bond and the fermion on site 3. The other two eigenstates can be obtained similarly.

We next prove that in the braiding process given in the main text there is always a pair of MZM at exactly zero energy. Without loss of generality we consider the $\phi_1 \rightarrow \phi_2$ step. The Hamiltonian in the fermion basis becomes

$$\begin{aligned} H &= -e^{ix} c_1^\dagger c_2 + c_1 c_2 + e^{-ix} c_1 c_2^\dagger - c_1^\dagger c_2^\dagger \\ &\quad - e^{-\frac{\pi}{3}i} c_2^\dagger c_3 + e^{\frac{2\pi}{3}i} c_2 c_3 + e^{\frac{\pi}{3}i} c_2 c_3^\dagger - e^{-\frac{2\pi}{3}i} c_2^\dagger c_3^\dagger \\ &\quad + e^{(-\frac{\pi}{3}-x)i} c_1 c_3^\dagger - e^{-\frac{2\pi}{3}i} c_1 c_3 - e^{(\frac{\pi}{3}+x)i} c_1^\dagger c_3 + e^{\frac{2\pi}{3}i} c_1^\dagger c_3^\dagger \end{aligned} \quad (15)$$

where we have temporarily omitted the energy unit t . We then have

$$[c_1^\dagger, H] = c_2 + e^{-ix} c_2^\dagger + e^{(-\frac{\pi}{3}-x)i} c_3^\dagger - e^{-\frac{2\pi}{3}i} c_3 \quad (16)$$

$$[c_1, H] = -[c_1^\dagger, H]^\dagger = -e^{ix} \left[c_2 + e^{-ix} c_2^\dagger - e^{-\frac{2\pi}{3}i} c_3 + e^{(-\frac{\pi}{3}-x)i} c_3^\dagger \right]$$

Therefore

$$[e^{\frac{ix}{2}} c_1^\dagger + e^{-\frac{ix}{2}} c_1, H] = 0 \quad (17)$$

Namely we have an MZM:

$$\tilde{a}_1 \equiv e^{\frac{ix}{2}} c_1^\dagger + e^{-\frac{ix}{2}} c_1 = C_{\frac{x}{2}} a_1 + S_{\frac{x}{2}} b_1 \quad (18)$$

To find the other MZM, we calculate the commutators between the other fermion operators with the Hamiltonian:

$$[c_2^\dagger, H] = e^{ix} c_1^\dagger - c_1 - e^{-\frac{i\pi}{3}} c_3 + e^{\frac{i\pi}{3}} c_3^\dagger \quad (19)$$

$$[c_2, H] = -e^{-ix} c_1 + c_1^\dagger + e^{\frac{i\pi}{3}} c_3^\dagger - e^{-\frac{i\pi}{3}} c_3$$

$$[c_3^\dagger, H] = e^{-\frac{i\pi}{3}} c_2^\dagger + e^{-\frac{i\pi}{3}} c_2 - e^{\frac{i\pi}{3}} c_1 + e^{i(\frac{\pi}{3}+x)} c_1^\dagger$$

$$[c_3, H] = -e^{\frac{i\pi}{3}} c_2 - e^{\frac{i\pi}{3}} c_2^\dagger + e^{-\frac{i\pi}{3}} c_1^\dagger - e^{-i(\frac{\pi}{3}+x)} c_1$$

Therefore

$$[c_2 - c_2^\dagger, H] = (1 - e^{-ix}) c_1 + (1 - e^{ix}) c_1^\dagger \quad (20)$$

$$[(e^{\frac{i\pi}{6}} c_3 - e^{-i\frac{\pi}{6}} c_3^\dagger), H] = e^{\frac{i\pi}{6}} (1 - e^{-i(\frac{\pi}{3}+x)}) c_1 + e^{-\frac{i\pi}{6}} (1 - e^{i(\frac{\pi}{3}+x)}) c_1^\dagger$$

However, the ratio between the coefficients of c_1 or c_1^\dagger in the two commutators above is purely real:

$$-\frac{1 - e^{-ix}}{e^{\frac{i\pi}{6}} (1 - e^{-i(\frac{\pi}{3}+x)})} = -\frac{2 - 2\cos x}{e^{\frac{i\pi}{6}} (1 - e^{-i(\frac{\pi}{3}+x)}) (1 - e^{ix})} = \frac{1 - \cos x}{\cos(x + \frac{\pi}{6}) - \frac{\sqrt{3}}{2}} \quad (21)$$

Thus the following Majorana operator commutes with the Hamiltonian and is the second MZM:

$$\begin{aligned} \tilde{b}_{23} &\equiv -iN \left(\left[\cos\left(x + \frac{\pi}{6}\right) - \frac{\sqrt{3}}{2} \right] (c_2 - c_2^\dagger) + (1 - \cos x) \left(e^{\frac{i\pi}{6}} c_3 - e^{-\frac{i\pi}{6}} c_3^\dagger \right) \right) \\ &= N \left(\left[\cos\left(x + \frac{\pi}{6}\right) - \frac{\sqrt{3}}{2} \right] b_2 + (1 - \cos x) \left(\frac{1}{2} a_3 + \frac{\sqrt{3}}{2} b_3 \right) \right) \end{aligned} \quad (22)$$

where N is a normalization factor. When $x = 0$ only the first term survives since

$$\lim_{x \rightarrow 0} \frac{1 - \cos x}{\cos(x + \frac{\pi}{6}) - \frac{\sqrt{3}}{2}} = 0 \quad (23)$$

while when $x = -\frac{\pi}{3}$ only the second term survives. So \tilde{b}_{23} continuously evolves from b_2 to $\frac{1}{2}a_3 + \frac{\sqrt{3}}{2}b_3$ along the path $\phi_1 \rightarrow \phi_2$.

II. MANY-BODY BERRY PHASE CALCULATION FOR THE 3-SITE KITAEV TRIANGLE

In this section we provide details for calculating the many-body Berry phase for braiding two MZM in the Kitaev triangle, as shown in Fig. 2 in the main text. To start we use the Hamiltonian Eq. (1) in the main text,

$$\mathcal{H} = \sum_{\langle jl \rangle} (-te^{i\phi_{jl}} c_j^\dagger c_l + \Delta e^{i\theta_{jl}} c_j c_l + \text{h.c.}) - \sum_j \mu c_j^\dagger c_j, \quad (24)$$

and write the creation and annihilation operators in the following Fock space basis for three spinless fermions

$$\begin{aligned}
(|0\rangle, |1\rangle, \dots, |7\rangle) &\equiv \{|n_1, n_2, n_3\rangle\} \\
&= (|0, 0, 0\rangle, \\
&\quad |1, 0, 0\rangle, |0, 1, 0\rangle, |0, 0, 1\rangle, \\
&\quad |0, 1, 1\rangle, |1, 0, 1\rangle, |1, 1, 0\rangle, \\
&\quad |1, 1, 1\rangle)
\end{aligned}$$

The creation(annihilation) operators in this space are defined as

$$\begin{aligned}
c_j^\dagger |n_1, \dots, n_j, \dots\rangle &= \sqrt{n_j + 1} (-1)^{s_j} |n_1, \dots, n_j + 1, \dots\rangle, \\
c_j |n_1, \dots, n_j, \dots\rangle &= \sqrt{n_j} (-1)^{s_j} |n_1, \dots, n_j - 1, \dots\rangle,
\end{aligned} \tag{25}$$

where

$$s_j = \begin{cases} \sum_{l=1}^{j-1} n_l & j > 1 \\ 0 & j = 1 \end{cases} \tag{26}$$

For the initial configuration corresponding to ϕ_1 in Eq. (6) of the main text, diagonalizing the 8×8 BdG Hamiltonian in the above basis leads to two degenerate ground states that can be distinguished by the occupation number of the following fermion operator constructed from the two MZM at the two bottom vertices

$$c_M \equiv \frac{1}{2}(a_1 + ib_2), \quad n_M \equiv c_M^\dagger c_M \tag{27}$$

The two degenerate ground states for the initial configuration, denoted as $|0\rangle_i$ and $|1\rangle_i$, therefore satisfy

$$\begin{aligned}
n_M |0\rangle_i &= 0, \\
n_M |1\rangle_i &= |1\rangle_i
\end{aligned} \tag{28}$$

In practice, we first construct the operator R_{gs} as a 8×2 matrix by combining the two column eigenvectors of the two lowest-energy eigenstates of the initial BdG Hamiltonian:

$$R_{\text{gs}} \equiv (\psi_i, \psi'_i) \tag{29}$$

and then diagonalize the projected n_M operator:

$$U_n^\dagger (R_{\text{gs}}^\dagger n_M R_{\text{gs}}) U_n \equiv R_i^\dagger n_M R_i = \begin{pmatrix} 0 & \\ & 1 \end{pmatrix} \tag{30}$$

To carry out the Berry phase calculation we next need to adiabatically “rotate” the vector potential field by following the linearly interpolated closed parameter path described in the main text, which is discretized into $N + 1$ segments. At any given point labeled by j along the path, we diagonalize the corresponding Hamiltonian and construct the projection operator P_j using the two lowest-energy eigenvectors ψ_j, ψ'_j :

$$P_j \equiv \psi_j \otimes \psi_j^\dagger + \psi'_j \otimes \psi'^{\dagger}_j \tag{31}$$

where \otimes means tensor product. The 2×2 Berry phase matrix $M_{f \leftarrow i}$ for the given parameter path is then obtained as

$$M_{f \leftarrow i} = \lim_{N \rightarrow \infty} R_f^\dagger P_N P_{N-1} \dots P_1 R_i \tag{32}$$

where $R_f = R_i$ since the path is closed.

By using a large enough N we found the converged $M_{f \leftarrow i}$ matrix has only diagonal elements being nonzero, meaning the braiding only changes each ground state by a scalar phase factor. Their values are $(M_{f \leftarrow i})_{00} = e^{i0.118\pi}$ and $(M_{f \leftarrow i})_{11} = e^{-i0.382\pi} = e^{i(0.118-0.5)\pi}$.

We end this section by noting that the parameter path considered for the 3-site Kitaev triangle above is not equivalent to rotating a staggered vector potential but to separately manipulating the Peierls phases along the three edges. We have also done calculations for the latter case and found the two lowest-energy states fail to be degenerate everywhere along the parameter path, leading to non-standard relative Berry phases between the two initial states.

III. CORNER MZM IN FINITE-WIDTH HOLLOW TRIANGLES

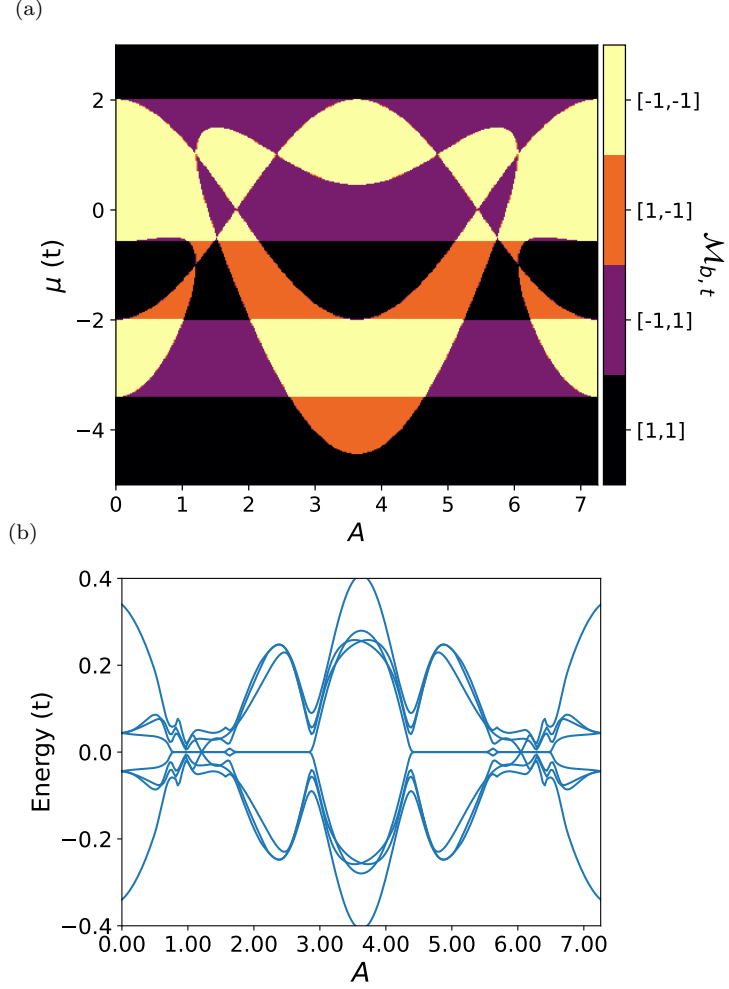

FIG. 1. (a) Topological phase diagram for a $W = 3$ hollow triangle obtained by overlapping the $\mathcal{M}_{b,t}(A, \mu)$ plots of 1D chains with $\mathbf{A} = A\hat{\mathbf{y}}$ and $\mathbf{A} = A(\frac{\sqrt{3}}{2}\hat{\mathbf{x}} + \frac{1}{2}\hat{\mathbf{y}})$. Color scheme: purple— $[\mathcal{M}_b, \mathcal{M}_t] = [1, 1]$, yellow— $[\mathcal{M}_b, \mathcal{M}_t] = [-1, -1]$, red— $[\mathcal{M}_b, \mathcal{M}_t] = [-1, 1]$, orange— $[\mathcal{M}_b, \mathcal{M}_t] = [1, -1]$ (b) Near-gap BdG eigen-energies vs A for a finite triangle with edge length $L = 80$, $W = 3$, and $\mu = 1.6$.

A model that is closer to a realistic hollow triangular island is the finite-width triangular chain or ribbon. An example, illustrated in Figure 1 (c), has its edge length $L = 50$ and width $W = 3$. The phase diagram Fig. 1 (a) is created in a similar way as that in Fig. 3 (a) of the main text, assuming a constant vector potential and infinitely long $W = 3$ ribbons. The spectral flow for the actual triangle with $\mu = 1.6$ in Fig. 1 (b) shows MZM in the parameter regions in agreement with the phase diagram. Fig. 1 (c) plots the MZM wavefunction for $A = 2.7409$ and $\mu = 1.6$ that are indeed well localized at the bottom corners.

We next rotate the uniform vector potential to examine how the MZM move on a hollow triangle. Figure 2 shows the spectral flow and eigenfunctions as we rotate $\varphi = 0$ to $\varphi = \pi$ counterclockwisely. The two MZM cycle through the three vertices in a similar manner as that in Fig. 4 of the main text (only the MZM wavefunctions at $\varphi = 0$ and $\frac{\pi}{3}$ are plotted as representatives of the $\varphi = n\pi/3$ cases). Note that the spectral flow has 3-fold rotation symmetry but not 6-fold, since increasing φ by $\frac{2\pi}{3}$ is equivalent to rotating the coordinate system clockwise by $\frac{2\pi}{3}$. In contrast, rotating the vector potential by $\frac{\pi}{3}$, if without an additional sign change of the p -wave pairing potential, is not an exact symmetry of the finite triangle. Also we did not try to scrutinize the phase diagram to find a parameter path in which the bulk gap does not close, as in the $W = 1$ case in the main text. Here we just point out that identifying a system-specific parameter path for adiabatic manipulation of MZM is in principle always possible, especially if one is allowed to have more knobs other than φ in real structures, such as tuning the chemical potential of individual edges

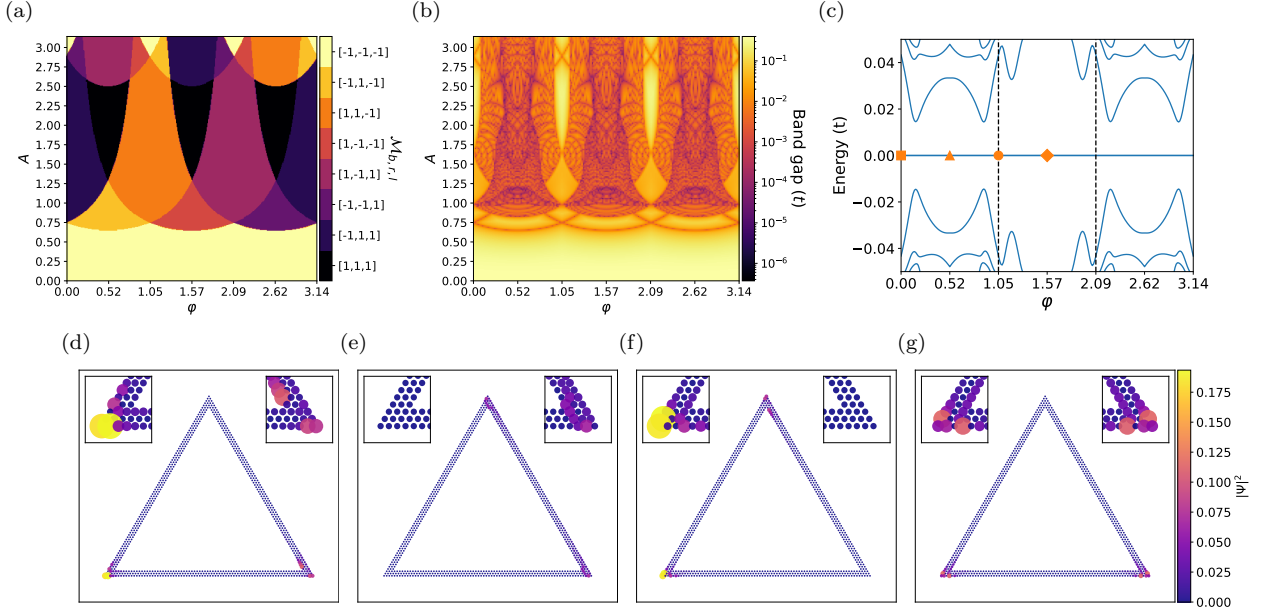

FIG. 2. (a) Topological phase diagram for a $W=3$ triangular ribbon with the Hamiltonian Eq. (5) by superimposing the $\mathcal{M}_{b,r,l}(\mu = 1.6, A, \varphi)$ plots of quasi 1D ribbons, $\varphi_{r,l}$ are out of phase with φ_b by $\pi/3$ and $-\pi/3$, respectively. (b) Bandgap size of the topological phase diagram, with both diagrams a path of vector potential strengths as a function of rotation angle allows for Majorana zero modes to persist throughout rotation. (c) Spectral flow of a hollow triangle with $W = 3, L = 80$, $\mu = 1.6$, and $\mathbf{A} = A(\varphi)(-\sin \varphi \hat{\mathbf{x}} + \cos \varphi \hat{\mathbf{y}})$ where a triangle wavefunction $A(\varphi) = A_{max} - 2(A_{max} - A_{min}) \left| \frac{\varphi}{\pi/3} - \left\lfloor \frac{\varphi}{\pi/3} - \frac{1}{2} \right\rfloor \right|$, $A_{max} = 0.83$ and $A_{min} = 0.77$, is used to prevent bandgap from opening. (d-g) BdG eigenfunction $|\Psi|^2$ summed over the two zero modes at $\varphi = [0, \frac{\pi}{6}, \frac{\pi}{3}, \frac{\pi}{2}]$.

or the size of the vector potential, etc.

IV. BRAIDING MZM IN A SMALL NETWORK OF TRIANGLES

In this section we show that one can braid two out of four MZM, a minimal setting for nontrivial manipulation of the degenerate many-body ground states, by using a small network of corner-sharing triangles. We focus on the critical step of swapping γ_2 and γ_3 as labeled in Fig. 5 of the main text. This can be done by rotating the vector potential of the triangle in the middle of the bottom row from $\varphi = \frac{\pi}{6}$ to $\frac{\pi}{3}$. More specifically, when $\varphi = \frac{\pi}{6}$, with the chosen values of μ and A , only the right edge of the said triangle is topologically nontrivial. The chain that hosts $\gamma_{3,4}$ thus extends through this nontrivial edge to the top triangle as in Fig. 3 (b). On the other hand, when φ increases to $\frac{\pi}{3}$, the nontrivial edge of the middle triangle changes from right to left, which leads to γ_2 hopping from its left corner to the right through the top corner, while γ_3 is unaffected [Figs. 3 (c-g)]. As a result the γ_2, γ_3 swapping is done without closing the bulk gap, as can be seen from the spectral flow in Fig. 3 (a).

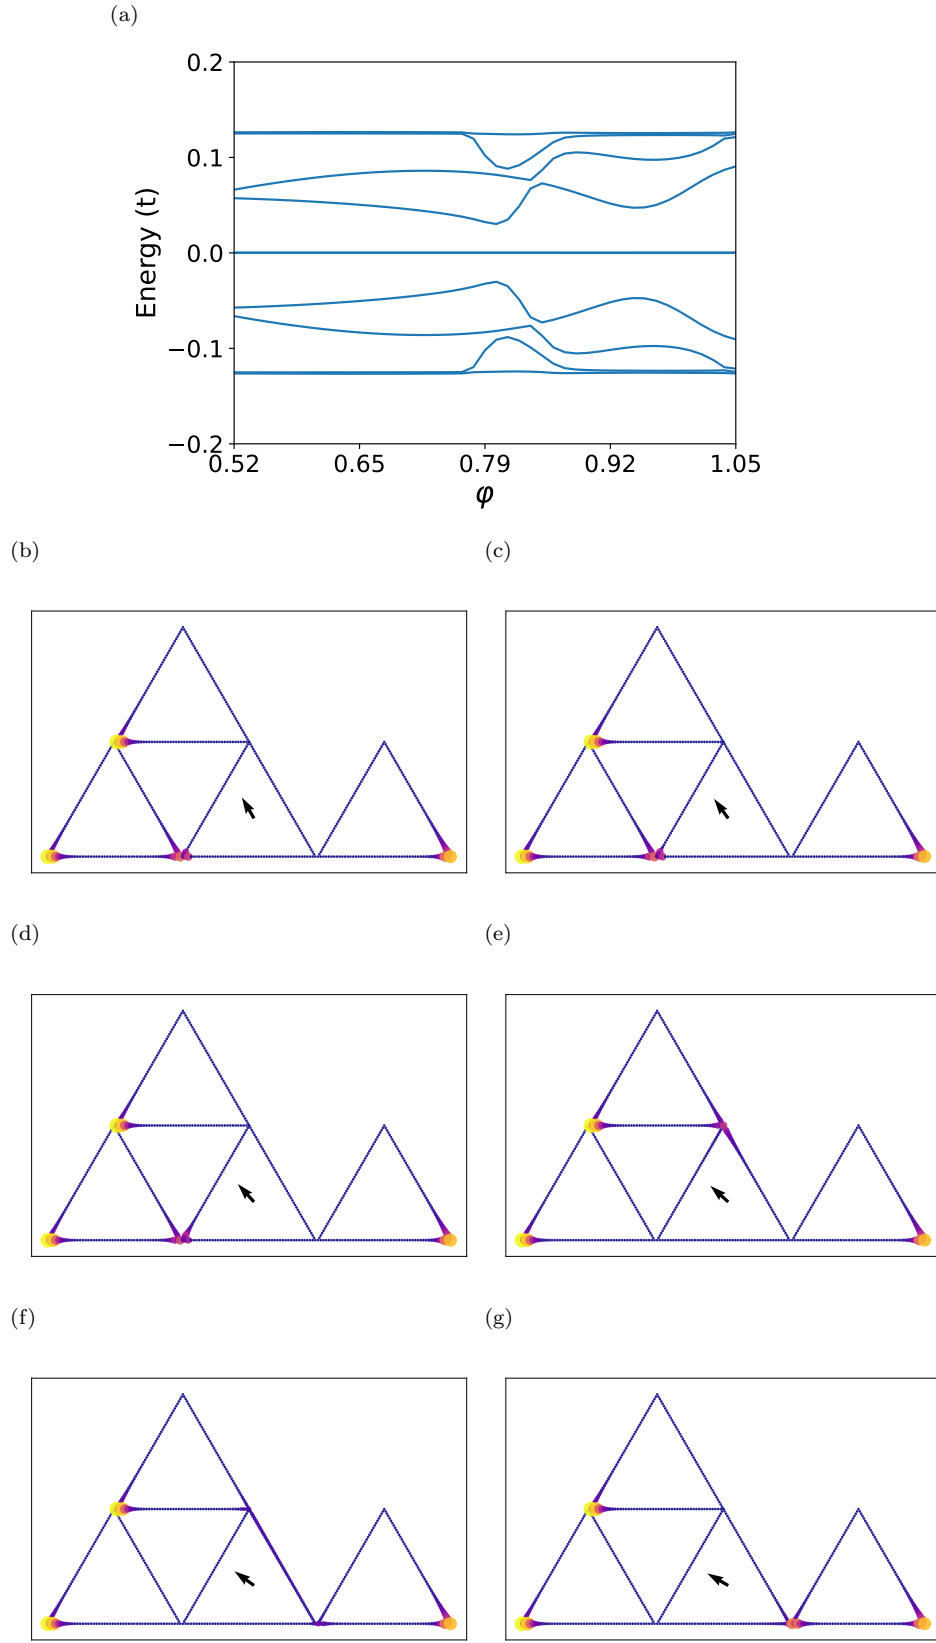

FIG. 3. (a) Spectral flow for the critical step of swapping γ_2 and γ_3 in the example of Fig. 5 in the main text, calculated using four corner-sharing triangles of $W = 1$ and $L = 50$, with $\mu = 1.6$ and $A = 2.6$. Vector potential for the middle triangle in the bottom row can rotate according to $\mathbf{A} = A(-\sin \varphi \hat{\mathbf{x}} + \cos \varphi \hat{\mathbf{y}})$ from $\varphi = \frac{\pi}{6}$ to $\frac{\pi}{3}$, while the other three have fixed $\varphi = 0$. (b)-(g) BdG eigenfunction $|\Psi|^2$ summed over the four zero modes at equally-spaced points along the rotation path. The black arrow indicates the direction of the vector potential for the bottom middle triangle.
